Atlas of ovine pathology

TECHNICAL DETAILS
Authors: Luis Miguel Ferrer, José Antonio García de Jalón and Marcelo De las Heras
Format: 20 x 29,5 cm
Number of pages: 312
Number of pictures: 900
Binding: Hardcover
ISBN: 978-84-932921-1-9
RRP: 120 €

This atlas compiles clinical cases and images of pathological conditions. It will be very helpful for any vet needing to recognise macroscopical and microscopical lesions in sheep.

Aimed at veterinary surgeons, students, teachers and other professionals in the veterinary sector.
# Atlas of ovine pathology

## TABLE OF CONTENTS

1. **Sucker lamb**  
   - Pathology of the newborn lamb  
   - Pathology of the digestive system  
   - Pathology of the respiratory system  
   - Pathology of the nervous system  
   - Ocular pathology  
   - Miscellaneous

2. **Feeder lamb and replacement ewes**  
   - Pathology of the digestive system  
   - Pathology of the respiratory system  
   - Circulatory system and haematopoietic system  
   - Nervous system  
   - Locomotor apparatus  
   - Urinary apparatus

3. **Adult sheep**  
   - Pathology of the digestive system  
   - Pathology of the respiratory system  
   - Pathology of the circulatory and haematopoietic systems  
   - Pathology of the nervous system  
   - Ocular pathology  
   - Pathology of the locomotor apparatus  
   - Pathology of the urinary apparatus  
   - Pathology of the skin and subcutaneous tissue  
   - Pathology of the male genital apparatus  
   - Pathology of the mammary gland  
   - Pathology of the female reproductive apparatus  
   - Obstetric and peripartum pathology  
   - Congenital defects, foetal malformations and foetal diseases

4. **Index**

5. **Index to the most common lesions found at slaughter**
1.27 - Enteric colibacillosis. Acute catarrhal enteritis. The yellowish content of these intestinal portions is much more watery than in the previous picture.

1.28 - Enteric colibacillosis. Initial stages of colibacillary diarrhoea. Examination of faeces may be of diagnostic value. Yellowish, highly mucous faeces are characteristic.

1.29 - Septicaemic colibacillosis. Septicaemic colibacillosis is characterised by a more acute clinical course than the enteric form. Many animals fail to progress to diarrhoea, and major symptoms include poor coordination (A), depression, confusion and recumbency; death occurs within a few hours (B).

1.30 - Septicaemic colibacillosis. Eyeball of a dead lamb (detail). Fibrin deposition is sometimes visible in the anterior chamber.
1.41 - Haemorrhagic enterotoxaemia. Open jejunum from a lamb with haemorrhagic enteritis. Note blood debris in gut lumen due to the action mainly of Clostridium perfringens type C toxins. Cl. perfringens type B strains may also occasionally be observed.

1.42 - Haemorrhagic enterotoxaemia. Open abomasum. Note digested blood, which has turned a dark colour.

1.43 - Haemorrhagic enterotoxaemia. Kidney surface and section, showing softened appearance and subcapsular bleeding.

Lamb dysentery

1.44 - Lamb dysentery. 12-day-old lamb. Perianal area stained with whitish faeces. Although faeces are initially whitish, they tend to darken as the disease progresses, due to blood content. This diarrhoea is common in lambs whose dams were not properly vaccinated against enterotoxaemia.

1.45 - Lamb dysentery. White diarrhoea. In its clinical phase, lamb dysentery is marked by the presence of white fluid faeces on the pen floor.

1.46 - Lamb dysentery. Distended intestinal loops containing whitish fluid faeces.
1.50 - Comparison of two lambs’ digestive tracts. Differential diagnosis: enterotoxaemia or dysentery (left) versus colibacillosis (right).

Cryptosporidiosis (Diarrhoea caused by Cryptosporidium parvum)

1.53 - Cryptosporidiosis. Animals with Cryptosporidium parvum infection. Feces are greenish, typically abundant and very watery, giving rise to marked dehydration. Onset is usually in the first week of life, and the clinical course may extend over the following 2 or 3 weeks. Infection is often combined with other intestinal agents (E. coli, Clostridium), which considerably aggravates morbidity and mortality.

1.54 - Cryptosporidiosis. Subacute catarrhal enteritis. Blind gut containing greenish matter, and hypertrophy of mesenteric lymph nodes.

1.51 - Colibacillosis and enterotoxaemia, combined lesions. Mixed infection by E. coli and Clostridium spp. may occasionally arise. In such cases, some portions of the gut display catarrhal enteritis, with yellowish content, while other portions show evidence of haemorrhagic enteritis.

1.52 - Intestinal loops distended by gas formation. In lambs over 3 weeks old, the action of the epsilon toxin produced by Cl. perfringens types B and D may prompt symptoms resembling those of adult enterotoxaemia. In such cases, tympanism of the gut is accompanied by foul luminal content.
2.12 - Ruminal acidosis in a replacement ewe lamb. Rumen contains abundant cereal grains; abomasal haemorrhage due to grain overload and acidosis.

2.13 - Ruminal acidosis. Rumenitis-multiple abscess complex. Ruminal acidosis favours the passage of ruminal bacteria that give rise to abscesses in the liver.

2.14 - Phytobezoars in the rumen. Numerous balls of plant fibres encrusted with mineral salts in a replacement ewe lamb fed an unbalanced diet.

2.15 - Tricobezoars in the abomasum of a replacement ewe lamb with ruminal acidosis. Barley grain overload and formation of black hairballs due to ingestion of pigmented wool resulting from a fibre-deficient diet. Note absence of hay or straw.

2.16 - Phytobezoars (A) and tricobezoars (B). Abomasum (detail). This frequent post-mortem finding may be attributed, among other things, to fibre- or mineral-deficient diet, overcrowding or other stressful situations.
2.37 - Coccidiosis. Subacute and chronic catarrhal enteritis. The gross appearance of the liver in coccidiosis may vary considerably, from thinning of the wall and formation of small nodules in the mucosa (A), to thickening of the wall and hypertrophy of mesenteric lymph nodes (B).

2.38 - Coccidiosis. Chronic hypertrophic catarrhal enteritis. Intestinal mucosa (detail), showing thickening of wall and folding of mucosa in portions of the ileum (A) and caecum (B).
